

Echoes of The Wind

For people who are not visually impaired, it's difficult to imagine the life of a blind person. With access to the right resources, blind people can lead a very normal life. However, lack of access to them can make them feel isolated in society.

Echoes of the wind takes these things into consideration. Sound acts as a major component in the pavilion to provide an interactive experience for visually impaired people and others as well. The wind blows through the hanging bamboos, generating a very audibly pleasing sound; a wide range of sounds can be produced by hitting the respective instrumental walls and the series of sounds and echoes create the notion of a concert atmosphere, thus bringing a sense of solidarity and mutual connection.

Sound / Materiality

The collages represent the theme of sound and materiality of surfaces, which are the most important elements when it comes to visually impaired persons, as those are the 2 elements that helped them to uncover the interesting elements of this world. Bamboo and timber are rich in variation and playability in the aspect of surface materials, hence the wide use of them in the design. Sound and wind have a common trait of not having a solid figure, and sound will not work without the presence of wind. Because of that, the idea of using wind to create sound through bamboo and timber was reflected through the collages.

Design Process

The intention was to create a pavilion that is made up of various kinds of musical instruments that introduce an extraordinary performance to visually impaired users. The pavilion creates an engagement not only to the users of the pavilion but the other users of the park also joins in part of the experience as park users walking around can feel the sound created through the parts of the pavilion.

Ventilation

Maximize the opening areas that allow natural wind flows to pass through, thus effecting the walls of hanging bamboos to create pleasant, mild, hollow, and clacking sounds by colliding onto one another.

Circulation

Spiral

Sound Intensity

Different areas create different intensity of sound from various instrumental walls, bringing a distinctive acoustic feeling to the users.

Bamboo Roof Structure
Different sizes of bamboo are used in the structure of the roof to minimize complications of material use.

Timber Roofing
The roof is covered in timber due to its versatility and contrast of colours and texture compared to the rest of the bamboo built parts.

Timber Columns
The supporting columns are made of timber which gives a very strong support to the structural system of the pavilion.

Concrete Footings
Concrete footing is used to distribute the pavilion weight and it has stronger durability which is able to resist weathering action.

Sound of the Bamboo

Mild, muted, hollow, clacking sounds produced when the wind blows through, convey a subtle and soothing atmosphere.

**Encouraging Interactions:
The Angklung Experience**

Angklung, a unique traditional instrument, that is positioned in the centre, encourages the users to coordinate with each other to play the melodies as well as allow them to recognize the instrument.

**Finding the right note:
The Xylophone**

Along the path, xylophones that are made by bamboos as compared to the other side of the instrumental wall, the Angklung, are being played together, which intends to produce a simple yet exceptional orchestra concert.
